*University of Texas at Austin*  
colinhu9@utexas.edu, garg@ece.utexas.edu

# Popular matching

- For a vertex  $v$ , we say  $v$  prefers  $M$  to  $M'$  if  $v$  prefers  $p_M(v)$  to  $p_{M'}(v)$ .
- $P(M, M') =$  the set of vertices that prefers  $M$  to  $M'$ . (Voting over matchings)
- “more popular than” relation  $\succ$  on  $M$ :

$$M' \succ M \text{ if } |P(M', M)| > |P(M, M')|.$$

## Definition

A matching  $M$  is **popular** if there is no matching  $M'$  such that  $M' \succ M$ .

# Housing allocation model

- The stable matching problem only makes sense in two-sided preference systems.
- The housing allocation model:
  - Bipartite graph  $G$
  - $\mathcal{A} \cup \mathcal{H}(\mathcal{P}) =$  set of agents(applicants) and set of houses(posts)
  - $E =$  set of edges
  - for each agent in  $\mathcal{A}$ , there is a strictly ordered preference lists over acceptable houses. Houses do not have preferences over agents.
- We will refer houses as posts and agents as applicants.

## NC model

- The set of decision problems decidable in polylogarithmic time on a parallel computer with a polynomial number of processors.
- Equivalently, a problem is in  $NC$  if there exist constants  $c$  and  $k$  such that it can be solved in time  $O(\log^c n)$  using  $O(n^k)$  parallel processors.
- $NC \subseteq P$

## Characterizing popular matchings

- **$f$ -post**: for each agent  $a$ , let  $f(a)$  denote the first-ranked post on  $a$ 's preference list.
- **$s$ -post**: let  $s(a)$  be the first non- $f$ -post on  $a$ 's preference list.
- **$l$ -post**: last-resort post.

$a_1 : p_1 \ p_4 \ p_5 \ p_2 \ p_6 \ l_1$   
 $a_2 : p_4 \ p_5 \ p_7 \ p_2 \ p_8 \ l_2$   
 $a_3 : p_4 \ p_1 \ p_3 \ p_8 \ l_3$   
 $a_4 : p_1 \ p_7 \ p_4 \ p_3 \ p_9 \ l_4$   
 $a_5 : p_5 \ p_1 \ p_7 \ p_2 \ p_6 \ l_5$   
 $a_6 : p_7 \ p_6 \ l_6$   
 $a_7 : p_7 \ p_4 \ p_8 \ p_2 \ l_7$   
 $a_8 : p_7 \ p_4 \ p_1 \ p_5 \ p_9 \ p_3 \ l_8$

# Characterizing popular matchings

## Theorem (Abraham, Irving, Kavitha and Mehlhorn)

*A matching  $M$  is popular if and only if*

- (i) every  $f$ -post is matched in  $M$ , and*
- (ii) for each applicant  $a$ ,  $M(a) \in \{f(a), s(a)\}$ .*

## High level ideas

- For each applicant  $a$ , only need to consider  $a$ 's f-post and s-post. Hence we can obtain a reduced graph that is sparse.
- Find a matching that is complete for the applicants.
- Locally rearrange to make sure every f-post is matched.

# Algorithm: popular matching

---

## Algorithm 1: Popular Matching

---

```
1 Input: Graph  $G = (\mathcal{A} \cup \mathcal{P}, E)$ .
2 Output: A popular matching  $M$  or determine that no such matching.
3
4  $G' :=$  reduced graph of  $G$ ;
5 if  $G'$  admits an applicant-complete matching  $M$  then
6   for each  $f$ -post  $p$  unmatched in  $M$  in parallel do
7     let  $a$  be any applicant in  $f^{-1}(p)$ ;
8     promote  $a$  to  $p$  in  $M$ ;
9   return  $M$ ;
10 else
11   return "no popular matching";
```

---

## Algorithm: Applicant-Complete Matching

- Finding an applicant-complete matching sequentially is easy through augmenting path.
- The degree of each agent is exactly two.
- Finding maximal paths can be done in NC.

# Algorithm: Applicant-Complete Matching

---

## Algorithm 2: Applicant-Complete Matching

---

```
1 Input: Graph  $G' = (\mathcal{A} \cup \mathcal{P}, E')$ .
2 Output: An applicant-complete matching  $M$  or determine that no such
  matching exists.
3  $M := \emptyset$ ;
4 while some post  $p$  has degree 1
5   For all such  $p$ , find maximal paths that end at  $p$ ;
6   for each edge  $(p', a')$  at an even distance from some  $p$  in parallel do
7      $M := M \cup \{(p', a')\}$ ;
8      $G' := G' - \{(p', a')\}$ ;
9 end while
10 for each post  $p$  has degree 0 in parallel do
11    $G' := G' - p$ 
12 // Every post now has degree at least 2;
13 // Every applicant still has degree 2;
14 if  $|\mathcal{P}| < |\mathcal{A}|$  then
15   return "no applicant-complete matching";
16 else
17   //  $G'$  decomposes into a family of disjoint even cycles
18    $M' :=$  any perfect matching of  $G'$ ;
19   return  $M \cup M'$ ;
```

## Complexity

### Lemma

*The while loop (line 4 in Algorithm 2) runs  $O(\log(n))$  number of rounds.*

### Proof.

- In round  $r$ , suppose we have  $t$  vertices of degree 1.
- Such vertices have degree at least 3 in round  $r - 1 \implies \geq 2t$  vertices are deleted.
- Totally  $\geq (2^r - 1)t$  vertices deleted  $\implies$  at most  $\lceil \log(n) \rceil + 1$  rounds.

□

### Theorem

*There is an NC algorithm to find a popular matching, or determine that no such matching exists.*

# Maximum-cardinality popular matching

- Popular matchings may have different sizes.
- Switching graph captures all the possible popular matchings.

# Switching graph

## Definition

Given a popular matching  $M$ , the switching graph  $G_M$  of  $M$  is a directed graph with a vertex for each post  $p$ , and a directed edge  $(p_i, p_j)$  for each agent  $a$ , where  $p_i = M(a)$  and  $p_j = O_M(a)$ .  $O_M(a)$  is the unmatched post in  $\{f(a), s(a)\}$ .

Figure: The switching graph  $G_M$  for popular matching  $M$

## Switching graph

### Lemma (McDermid and Irving, Lemma 1)

Let  $M$  be a popular matching for an instance of  $G = (\mathcal{A} \cup \mathcal{P}, E)$ ,  $G_M$  be the switching graph of  $M$ . Then

- (i) Each vertex in  $G_M$  has outdegree at most 1.
- (ii) The sink vertices of  $G_M$  are those vertices corresponding to posts that are unmatched in  $M$ , and are all  $s$ -post vertices.
- (iii) Each component of  $G_M$  contains either a single sink vertex or a single cycle.

## Cycle components and tree components

- A component of a switching graph  $G_M$  is called a *cycle component* if it contains a cycle, and a *tree component* if it contains a sink vertex.
- Each cycle in  $G_M$  is called a *switching cycle*.
- If  $T$  is a tree component of  $G_M$  with sink vertex  $p$ , and if  $q$  is another  $s$ -post vertex in  $T$ , the unique path from  $q$  to  $p$  is called a *switching path*.
- Note that each cycle component of  $G_M$  has a unique switching cycle, but each tree component may have zero or multiple switching paths.

## Findings cycles in Pseudoforest

### Definition

A **pseudoforest** is an undirected graph in which every connected component has at most one cycle. A **directed pseudoforest** is a directed graph in which each vertex has at most one outgoing edge, i.e., it has outdegree at most one.

## Transitive closure

### Theorem (Hirschberg)

*The transitive closure of a directed graph with  $n$  vertices can be computed in  $O(\log^2 n)$  time, using  $O(n^\omega \log n)$  operations on a CREW PRAM, where  $n^\omega$  is the best known sequential bound for multiplying two  $n \times n$  matrices over a ring.*

We compute the transitive closure  $G_P^*$  and for any two vertices  $i$  and  $j$  s.t.  $i \neq j$  in  $G_P$ , if  $G_P^*(i, j) = 1$  and  $G_P^*(j, i) = 1$ , then both  $i$  and  $j$  are in the unique cycle  $C$ . Hence we can identify the cycle  $C$  by checking each pair of vertices in parallel.

## Algorithm: maximum-cardinality popular matching

### Definition

Let  $\Delta$  be the margin of applying a switching cycle  $C$  (resp. switching path  $P$ ) to  $M$ , i.e.

$$\Delta = \sum_{a \in C(\text{resp. } P)} \mathbb{1}_{M \cdot C(a)} - \mathbb{1}_{M(a)}$$

where  $\mathbb{1}_p$  is an indicator function of posts

$$\text{s.t. } \mathbb{1}_p := \begin{cases} 1 & \text{if } p \text{ is not } l\text{-post} \\ 0 & \text{if } p \text{ is } l\text{-post} \end{cases}$$

Figure: A tree component in switching graph

# Algorithm: maximum-cardinality popular matching

---

## Algorithm 3: Maximum-Cardinality Popular Matching

---

- 1 Input: Reduced graph  $G' = (\mathcal{A} \cup \mathcal{P}, E')$  and a popular matching  $M$ .
  - 2 Output: A maximum-cardinality popular matching  $M'$ .
  - 3
  - 4  $G_M :=$  switching graph of  $M$  and  $G'$ .
  - 5 Find all weakly connected components of  $G_M$ ;
  - 6 **for each cycle component in parallel do**
  - 7     Find the unique switching cycle;
  - 8 **for each switching cycle in parallel do**
  - 9     Compute the margin of applying this switching cycle;
  - 10 **for each cycle component in parallel do**
  - 11     if the margin  $\Delta$  of switching cycle is positive
  - 12         Apply this switching cycle to  $M$ ;
  - 13 return  $M'$ ;
-

## Correctness

### Theorem (McDermid and Irving, Corollary 1)

*Let the tree components of  $G_M$  be  $T_1, \dots, T_k$ , and the cycle components of  $G_M$  be  $C_1, \dots, C_l$ . Then the set of popular matchings for  $G$  consists of exactly those matchings obtained by applying at most one switching path in  $T_i$  and by either applying or not applying the switching cycle in  $C_i$ .*

- Any popular matching can be obtained from  $M$  by applying at most one switching cycle or switching path per component of the switching graph  $G_M$ .

### Theorem

*For each tree component  $T$ , applying the switching path in  $T$  with the largest positive margin; similarly, for each cycle component  $C$ , applying the switching cycle in  $C$  with positive margin, the new matching is the maximum-cardinality popular matching.*

## Complexity

- The switching graph  $G_M$  can be constructed from  $G'$  and  $M$  in constant time in parallel.
- All weakly connected components of  $G_M$  can also be found in polylog time.
- All switching cycles and switching paths can be found in polylog time. Each switching cycle and switching path can be applied to matching  $M$  easily in parallel since they are vertex-disjoint in  $G_M$ .

### Theorem

*There is an NC algorithm to find a maximum-cardinality popular matching, or determine that no such matching exists.*
